Abstract

Today agriculture is a key source of livelihood for around 50% of people in India. To bring positive growth in India's GDP modifications in the agriculture industry are required. Every other field possesses some new technologies as compared to the agricultural field. Around 42% of the farm produce goes to waste due to the inability of farmers to detect and take precautions against plant leaf diseases. In this paper we have devised a technique to overcome this issue, this plant leaf disease detection technique can be used to detect the disease from input images. It uses steps like image pre-processing, image segmentation, feature extraction. This will be helpful to maintain the better quality of the farm produce and decrease the amount of produce that goes to waste due to undetected diseases.

Chapter 1

Introduction

1.1 Overview

The primary source of income for the majority of people in India is agriculture. Due to the diverse climate all over India, a wide variety of crops are produced in India. The production of crops is affected by various factors such as climatic conditions, soil conditions, various diseases, etc. Currently, farmers rely on their eyes for detecting any plant disease which results in improper judgment and hampers the quality of the farm produce and, increases the amount of produce thrown in waste. Inefficient disease detection leads to improper pesticide usage that can cause the development of long-term resistance of the pathogens and resultantly reduces the ability of the crop to fight back. Plant leaf disease detection can be achieved by identifying various spots on the leaves of the affected plant. We will use image processing using the convolution neural network (CNN) to detect plant leaf diseases.

1.2 Motivation

Our aim here is to design such a system which detects whether a plant is having a disease or not by using image processing and CNN. The purpose of this project is to identify plant disease in an accurate and timely way so that it reduces the loss of the agricultural production and benefits the people in the best possible way.

1.3 Objective

The objective of our project is that, the website that we have developed should be easily available for the farmers and other people as well. So that by using our website they can understand if the plant is having a disease or healthy, that too with higher efficiency and maximum accuracy. If the plant have a disease, proper remedies are also provided in our website.

Chapter 3

Problem Statement

3.1 Justification of Problem

We have proposed a plant leaf disease detection technique using ResNet152 CNN architecture. We also compared our proposed system with several traditional classification methods. The proposed method achieves better accuracy of classification (94.01%) as compared to the best competitive method. Since transfer learning is used, the proposed approach produces good classification results without the need to train deep neural networks from the ground up. Also we give the proper remedies to the leaf which have a disease.

3.2 Need for the New System

Today agriculture is a key source of livelihood for around 50% of people in India. To bring positive growth in India's GDP modifications in the agriculture industry are required. Every other field possesses some new technologies as compared to the agricultural field. Around 42% of the farm produce goes to waste due to the inability of farmers to detect and take precautions against plant leaf diseases. In this paper we have devised a technique to overcome this issue, this plant leaf disease detection technique can be used to detect the disease from input images. It uses steps like image pre-processing, image segmentation, feature extraction. This will be helpful to maintain the better quality of the farm produce and decrease the amount of produce that goes to waste due to undetected diseases.

3.3 Existing System

In the existing system, it only classifies if the plant is having a disease or not but in our system, we also tell the user about the information, symptoms and cause for the disease. Also, the previous system shows maximum accuracy of 92.3% but our system predicts tomato plant leaf disease with 94.01% of accuracy.

Chapter 4

Project Requirement Specification

4.1 Software Requirements

4.1.1 Purpose

The purpose of this project is to identify plant disease in an accurate and timely way so that it reduces the loss of the agricultural production and benefits the people in the best possible way.

4.1.2 Intended Audience

The intended audience for our project is farmers apart from this other individuals can also use it for planting purpose.

4.1.3 System Feature 1

The first feature of our project is that, it is used for the classification of the tomato plant leaf and gives the output as, the leaf is diseased or healthy.

Description and Priority

This is a high priority feature as it is the main part of our project and classifies that the tomato plant leaf has disease or not. Also the benefit of this feature is that it gives accuracy of 94.01%.

4.1.4 System Feature 2

The second feature of our project is that, after the classification is done, it also gives the information about the disease and proper remedies are given accordingly. It also gives us the preventions for various diseases.

7.2 Algorithm

Convolution Neural Networks (CNN)

Deep learning is a class of machine learning algorithms that has sequential layers. Every layer utilizes the output of the previous layer as input. This learning process can be supervised, unsupervised or semi-supervised. Deep learning does not have to divide the feature extraction and the classification separately since the model automatically extracts the features while training the model. It is used in many research areas such as image restoration, image processing, natural language processing, speech recognition and, bioinformatics. In this study, we prefer CNN as a Deep Learning method. Convolutional Neural Network (CNN) is a Deep Learning algorithm that takes in an input image, assigns importance (learnable weights and biases) to various aspects/objects in the image and, can differentiate one aspect from another. The pre-processing required in a CNN is much lower in comparison to other classification algorithms. The architecture of a CNN is similar to the neuron connections in a human brain.

It has 4 main layers:

1. Convolutional layer
2. Pooling layer
3. Activation function layer
4. Fully connected layer

7.3 Methodologies

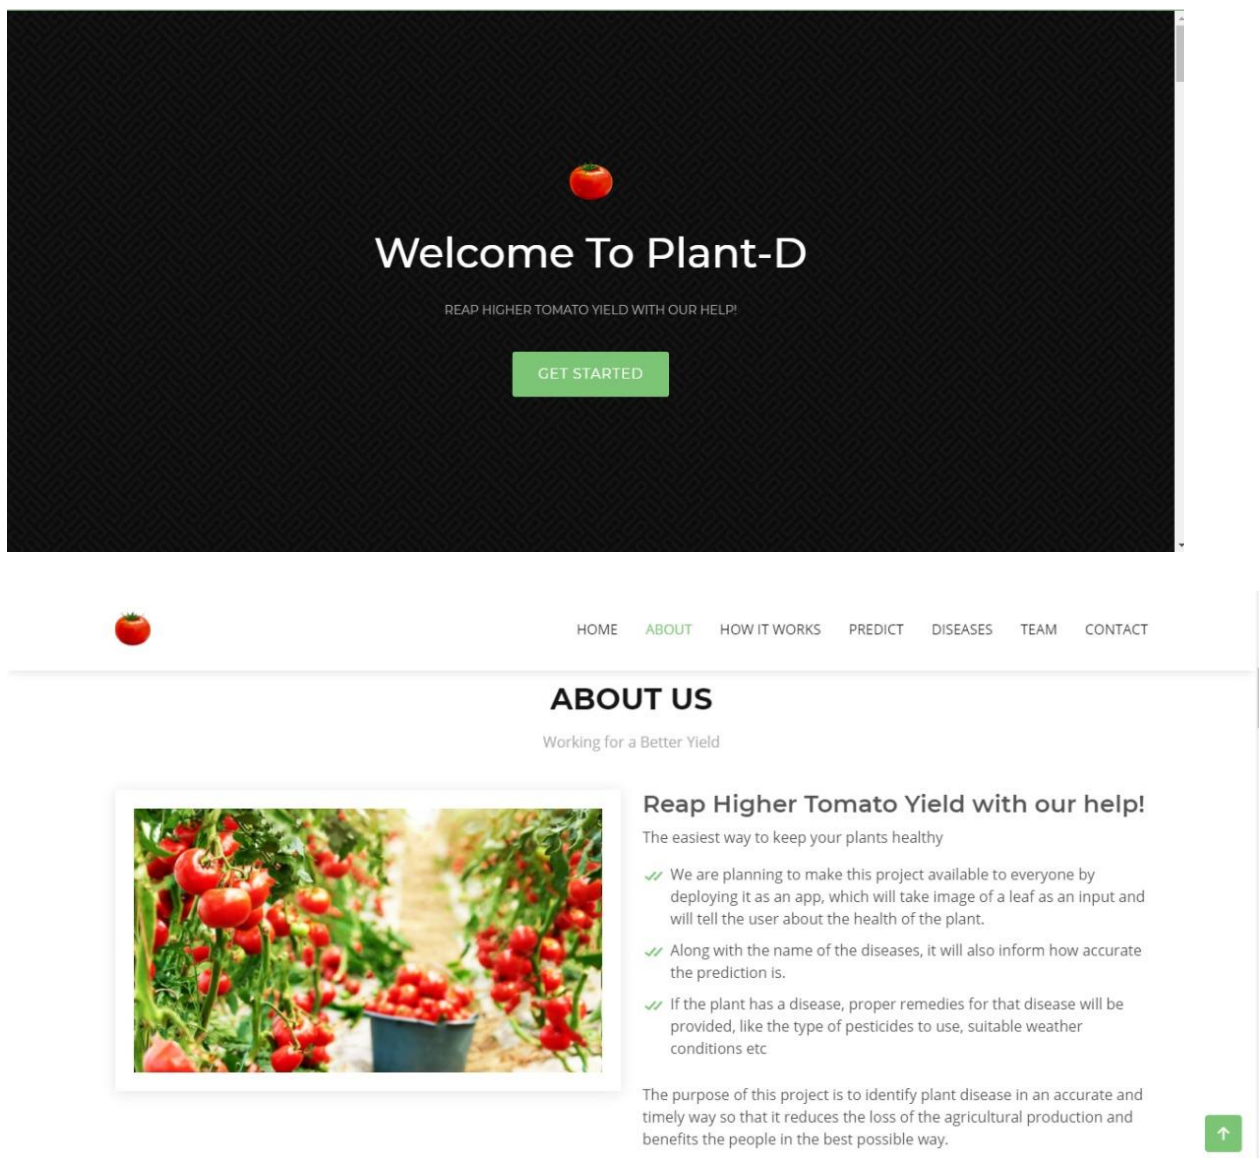

In this study, 15745 training and 4000 test tomato leaf images have been used from the Tomato Leaf dataset (Kaggle). The images in the selected dataset have been cropped to the size of 224x224. The intended leaf diseases to classify in this study are late blight, early blight, bacterial spot, leaf mold, Septoria leaf spot, target spot, mosaic virus, yellow leaf curl. Nine different classes have been used, eight of them are for leaf diseases and one of them is for healthy leaves.

- **Early Blight** - Initially, leaves have small dark spots form on older foliage near the ground. Leaf spots are round, brown, and can grow up to half an Early Blight - Initially, leaves have small dark spots form on older foliage near the ground. Leaf spots are round, brown and can grow up to half-inch in diameter. Larger spots have target like concentric rings. The tissue around spots often turns yellow
- **Late Blight** - Leaves have large, dark brown blotches with a green-gray edge; not confined by major leaf veins. Stem infections are firm and dark brown with a rounded edge.
- **Septoria Leaf Spot** - Septoria leaf spots start somewhat circular and first appear on the undersides of older leaves, at the bottom of the plant. They are small, 1/16 to 1/8 inches (1.6 to 3.2 millimeters) in diameter, with a dark brown margin and lighter gray or tan centers. A yellow halo may surround the spot. As the disease develops, the spots will get larger and may merge.
- **Bacterial Spot** - Leaf lesions are initially circular and water-soaked and may be surrounded by a faint yellow halo. In general, spots are dark brown to black and circular on leaves and stems. Spots rarely develop to more than 3 mm in diameter. Lesions can coalesce causing a blighted appearance of leaves and a general yellowing may occur on leaves with multiple lesions. Tomato Yellow Leaf Curl - Leaves of infected plants are small and curl upward, and show strong crumpling and interveinal and marginal yellowing. The internodes of infected plants become shortened and, together with the stunted growth, plants often take on a bushy appearance, which is sometimes referred to as 'bonsai' or broccoli'- like growth.
- **Leaf Mold** - Symptoms of the disease include yellow spots on the upper leaf surface. Discrete masses of olive green spores can be seen on the underside of the affected leaves. The older leaves become infected first and die prematurely. The pathogen may spread rapidly during periods of prolonged relative humidity.
- **Target Spot** - The disease starts on the older leaves and spreads upwards. The first signs are irregular-shaped spots (less than 1 mm) with a yellow margin. Some of the spots enlarge up to 10 mm and show characteristics rings, hence the name of "target spot". Spread to all leaflets and other leaves are rapid, causing the leaves to turn yellow, collapse, and die.
- **Tomato Mosaic Virus** - Mottled light and dark green on leaves. If plants are infected early, they may appear yellow and stunted overall. Leaves may be curled, malformed, or reduced in size. Spots of dead leaf tissue may become apparent with certain cultivars at warm temperatures. Fruits may ripen unevenly.

DISEASES

Early Blight

Early blight is a common tomato disease caused by the fungus *Alternaria solani*. It can affect almost all parts of the tomato plants, including the leaves, stems, and fruits. The plants may not die, but they will be weakened and will set fewer tomatoes than normal. Early blight generally

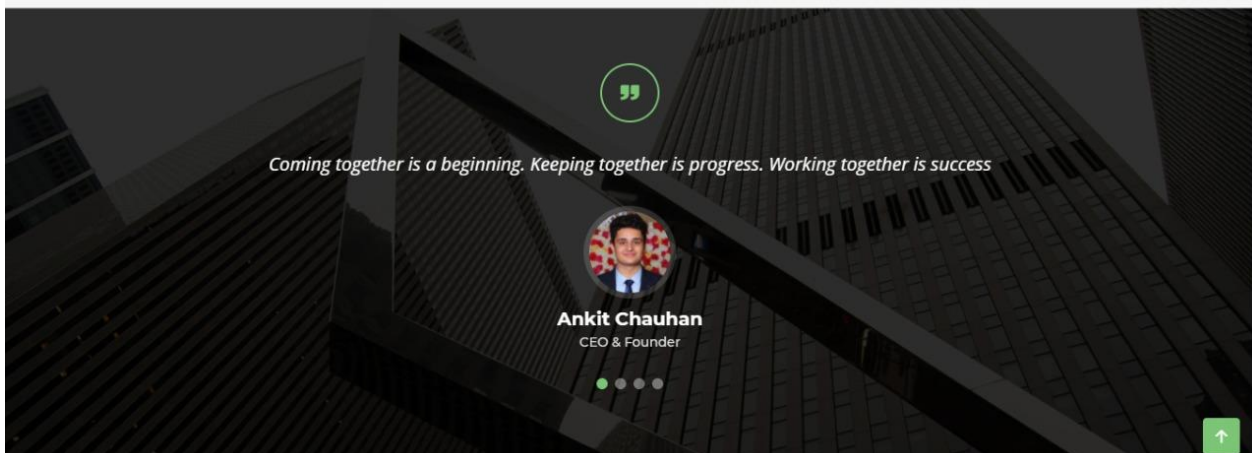

Late Blight

Tomatoes are especially susceptible to an affliction known as late blight. Characterized by large, irregularly-shaped, greasy gray spots, Although plants infected with late blight tend to die quickly, you can often salvage some of your tomatoes from the plant before they reach their

Septoria Leaf Spot

Septoria leaf spot is a very common disease of tomatoes. It is caused by *Septoria lycopersici* and can affect tomatoes and other plants in the Solanaceae family. Although Septoria leaf spot is not necessarily fatal for your tomato plants, it spreads rapidly and can quickly defoliate and

Tomato Plant Leaf Disease Classification

Select a Tomato leaf Image...

Prediction : Tomato - Late Blight

LATE BLIGHT

PHYTOPHTHORA INFESTANS

Late Blight (Phytophthora Infestans)

Late blight is a potentially devastating disease of tomato and potato, infecting leaves, stems and fruits of tomato plants. The disease spreads quickly in fields and can result in total crop failure if untreated.

Late Blight (Phytophthora Infestans)

Late blight is a potentially devastating disease of tomato and potato, infecting leaves, stems and fruits of tomato plants. The disease spreads quickly in fields and can result in total crop failure if untreated.

Cause

Late blight is caused by the oomycete *Phytophthora infestans*. Oomycetes are fungus-like organisms also called water molds, but they are not true fungi. There are many different strains of *P. infestans*. These are called clonal lineages and designated by a number code (i.e. US-23). Many clonal lineages affect both tomato and potato, but some lineages are specific to one host or the other. The host range is typically limited to potato and tomato, but hairy nightshade (*Solanum physalifolium*) is a closely related weed that can readily become infected and may contribute to disease spread. Under ideal conditions, such as a greenhouse, petunia also may become infected.

Symptoms

- Leaves have large, dark brown blotches with a green gray edge; not confined by major leaf veins.
- In the greenhouse, discard trays adjacent to outbreak location to minimize disease spread.
- Treat seeds with dilute bleach, hydrochloric acid, or hot water to reduce the potential for seedling infection. However, this seed treatment is not recommended for producers that use pelleted seeds as it will remove the pelleted coating from seeds. These treatments may also reduce seed germination. Perform a test treatment on approximately 50 to 100 seeds and check for the effect on germination before treating an entire seed lot.
- In transplant production greenhouses, minimize overwatering and handling of seedlings when they are wet.
- Trays, benches, tools, and greenhouse structures should be washed and sanitized between seedlings crops.

8.2 Experimental Results

The image given below is of a leaf having late blight disease.

Now to predict this, we provide the above image as an input to the system and following are the prediction results:-

Testing

9.1 Test Strategy

9.1.1 Unit Testing

Here we have used ResNet Algorithm, so for unit testing 15745 training and 4000 test tomato leaf images have been used from the Tomato Leaf dataset (Kaggle).

9.1.2 System Testing

Here we have tested 100 images from Google other than our dataset for individual disease.

9.1.3 Validation Testing

Our system was tested by 3-4 clients and they found it quite comfortable and easy to use.

9.2 Test Cases

- Whenever an image is uploaded by the user, the system will give output if the leaf is diseased or healthy.
- If the user provides different image other than the disease, the system will give output as disease not found.
- If the user provides an image with the format other than .jpg or .png then the system will not accept it.

9.3 Test Results

Chapter 10

Conclusion and Future Scope

10.1 Conclusion

We have proposed a plant leaf disease detection technique using ResNet152 CNN architecture. We also compared our proposed system with several traditional classification methods. The proposed method achieves better accuracy of classification (94.01%) as compared to the best competitive method. Since transfer learning is used, the proposed approach produces good classification results without the need to train deep neural networks from the ground up.

10.2 Future Scope

- We are planning to make this project available to everyone by deploying it as an app, which will take image of a leaf as an input and will tell the user about the health of the plant.
- Along with the name of the diseases, it will also inform how accurate the prediction is.
- If the plant has a disease, proper remedies for that disease will be provided in the app, like the type of pesticides to use, suitable weather conditions etc.

10.3 Limitations of Project Work

The limitation of our project is that it does not classify other plant leaves, it only classifies the tomato plant leaf.

 **PaperRater**

Abstract—Today agriculture is a key source of livelihood for around 50% of people in India. To bring positive growth in India's GDP modifications in the agriculture industry are required. Every other field possesses some new technologies as compared to the agricultural field. Around 42% of the farm produce goes to waste due to the inability of farmers to detect and take precautions against plant leaf diseases. In this paper we have devised a technique to overcome this issue, this plant leaf disease detection technique can be used to detect the disease from input images. It uses steps like image pre-processing, image segmentation, feature extraction. This will be helpful to maintain the better quality of the farm produce and decrease the amount of produce... Word Choice

Usage of Bad Phrases

Bad Phrase Score: 1.29 (lower is better)

The Bad Phrase Score is based on the quality and quantity of trite or inappropriate words, phrases, egregious misspellings, and clichés found in your paper. You did equal or better than **95%** of the people in your grade.

Great job choosing quality phrases! Looks like you scored well above average.

Style

Usage of Transitional Phrases

Transitional Words Score: 48

This score is based on quality of transitional phrases used within your paper. You did equal or better than **22%** of the people in your grade.

Your usage of transitional phrases is below average. Please review the writing tips below.

One sign of an excellent writer is the use of transitional phrases (e.g. therefore, consequently, furthermore). Transitional words and phrases contribute to the *cohesiveness* of a text and allow the sentences to flow smoothly. Without transitional phrases, a text will often seem disorganized and will most likely be difficult to understand. When these special words are used, they provide organization within a text and lead to greater understanding and enjoyment on the part of the reader.

The following transitional phrases were found in your document:
lastly, and, since, finally, at the same time, thus, together with, generally, to begin with, in time, although, to summarize, moreover, on the contrary, on the other hand, subsequently

Consider using additional transitions where appropriate:

- consequently
- nevertheless
- notwithstanding
- accordingly
- conversely
- ordinarily

Transitional phrases may be used in various places in a text:

- between paragraphs
- between sentences
- between sentence parts
- within sentence parts

Consider this example:

I lost my money; **therefore**, I could not buy a ticket.

The word **'therefore'** contributes to greater unity or cohesion between sentences and allows the text to flow more smoothly.

II. Published Paper

II. CNN

Deep learning is a class of machine learning algorithms that has sequential layers. Every layer utilizes the output of the previous layer as input. This learning process can be supervised, unsupervised or semi-supervised. Deep learning does not have to divide the feature extraction and the classification separately since the model automatically extracts the features while training the model. It is used in many research areas such as image restoration, image processing, natural language processing, speech recognition and, bioinformatics. In this study, we prefer CNN as a Deep Learning method. Convolutional Neural Network (CNN) is a Deep Learning algorithm that takes in an input image, assigns importance (learnable weights and biases) to various aspects/objects in the image and, can differentiate one aspect from another. The pre-processing required in a CNN is much lower in comparison to other classification algorithms. The architecture of a CNN is similar to the neuron connections in a human brain.

Fig. 1. CNN MODEL

It has 4 important operations involved: 1. Convolution, 2. Pooling, 3. Activation functions and 4. Fully connected layer. Fig. 1 shows a general CNN architecture.

- Convolution - The name CNN is derived from this layer. The aim of this operation is to extract features from the input image. CNNs are not limited to only one Convolutional Layer. Conventionally, the first Convolutional Layer is responsible for capturing the low-level features such as edges, color, gradient orientation, etc. With the use of added layers, the architecture adapts to the high-level features as well, giving us a network that has a good understanding of images in the data set, similar to how a human brain would comprehend. The feature map of the input image is extracted by performing a series of mathematical operations on the input image. The input image is reduced to a smaller size by using a filter. The filter is shifted step by step commencing from the upper left corner of the image. At each step, the values in the image are multiplied by the values of the filter and the result is then summed. Resultantly, a new matrix with a smaller size is created from the input image [1]. Fig. 2 shows the convolution operation on a 5x5 input image using a 3x3 filter.

Fig. 2. CONVOLUTION OPERATION

- Pooling - Similar to the convolution operation, the operation of pooling is to reduce the spatial size of the convolved Feature. The size of the output matrix obtained from the convolution layer is reduced in this layer. Moreover, it is used for extracting the dominant features which are rotational and positional invariant, thus maintaining the process of effectively training the model. Although filters of different sizes can be used for pooling, generally 2x2 size filter is used [1]. Pooling operations can be of different types such as average pooling, max pooling and, minimum pooling can be used in this layer. In this research, max pooling and average pooling has been applied. Max pooling is achieved by selecting the maximum element from the region of the feature map covered by the filter. Hence, the output after max-pooling operation will be a feature map having the most prominent features of the previous feature map. Fig. 3 shows a pooling operation.

Fig. 3. AVERAGE POOLING OPERATION

- Activation Functions- The activation function is a node that is placed at the end or in the middle of a Neural Network. They play a role in determining whether or not a neuron can fire. The activation function in artificial neural networks creates a curvilinear relationship between the input and output layers. It has an effect on network efficiency. The activation function is used to achieve non-linear network learning. There are a variety of activation functions available, including linear, sigmoid, and hyperbolic tangent, but the nonlinear ReLU (Rectified Linear Unit) activation function is most commonly used in CNN. Values less than zero are set to zero in ReLU, while values greater than zero remain unchanged. Fig. 4 shows various activation functions.

Fig. 4. ACTIVATION FUNCTIONS

- Fully Connected Layers-The final obtained matrix is fed into the fully connected layer (also known as the dense layer) as input after the convolution, pooling, and activation operations are completed. This layer is in charge of learning the image's parameters. We apply an output layer at the end of the Dense Layer that classifies the images into their respective classes. We're using a SoftMax function in the Output layer. Fig. 5 shows the formula of the SoftMax function.

$$\sigma(\vec{z})_i = \frac{e^{z_i}}{\sum_{j=1}^K e^{z_j}}$$

Fig. 5. SoftMax FUNCTION

e^{z_j} -Standard exponential function for output vector

III. ResNet ALGORITHM

In this study, the ResNet algorithm also known as Residual Neural Network is used to train the data.

ResNet is a network structure proposed in 2015 by He Kaiming, Sun Jian, and others of Microsoft Research Asia in 2015, it won the first place in the ILSVRC-2015 classification task. It also took first place in the ImageNet detection, ImageNet localization, COCO detection, and COCO segmentation tasks at the same time.

ResNet, also known as Residual Neural Network, is a concept that combines residual learning with the traditional convolutional neural network to solve the problem of vanishing gradient and accuracy degradation (training set) in deep networks, allowing both accuracy and speed to be controlled as the network gets deeper and deeper.

The idea of residual learning is the Fig6, which can be understood as a block, defined as follows:

$$y = x + F(x, (W_i))$$

The residual learning block contains two branches or two mappings:

1. Identity mapping refers to the curve on the right side of Figure 6. As its name implies, identity mapping refers to its mapping, which is x itself;
2. F(x) Residual mapping refers to another branch, that is, part. This part is called residual mapping (y-x).

Fig. 6. WORKING OF ResNet

The idea behind Residual Networks is illustrated in Fig 7.

Fig. 7. IDEA BEHIND RESIDUAL NETWORKS

In Figure 7, The plain network only sends information from one layer to the next; information about the image's previous state is highly limited, and all activations must be based on new features; on the other hand, the residual connections take the feature map from layer T and adds it to the output of layer T+2. This is equal to learning the residual function $y = f(x) + x$. A layer T in a direct feed-forward network without residual connections relies solely on data from layer T-1, with layer T-1 encoding the consequences of all previous layers. Residual connections, on the contrary, look further back in time, taking into account information from layer T-2.

This very simple but powerful idea enables to train over a 100 layers network with increasing accuracy. Different variants of ResNet are shown in Figure 8.

Fig. 9. SAMPLE PHOTOS OF AFFECTED LEAVES

In this paper, we use transfer learning to implement a novel deep neural network architecture for tomato plant leaf disease detection. In the feature extraction layers of the proposed system, state-of-the-art CNN is used and its features are extracted. The extracted features are then given to fully connected layers to generate classification outputs.

A. Pretrained CNN for Feature Extraction

In this section, we adopt one deep CNN architecture, namely ResNet152 as the feature extractor of the proposed method for tomato plant leaf disease detection tasks. The CNN is pre-trained on a nature image data set (ImageNet) for distinct generic image descriptors and it can be applied to

extract discriminative features from biomedical images based on transfer learning theory. We select ResNet152 as it achieves the best accuracy among ResNet family members. Fig. 10 illustrates the basic architecture of ResNet152.

Fig. 10. ResNet152 ARCHITECTURE

B. The Proposed Network Structure

To begin with, the CNN model is trained over more than a million natural images from 1000 categories in ImageNet [9]. As discussed in [8], after being trained on a very large labelled dataset (e.g., ImageNet), transfer learning technique can be used, i.e., Deep CNNs can learn generic image features that can be applied to other image datasets without needing to be trained from scratch. Fig. 11 illustrates the transfer learning structure for a single CNN. In this figure, The pretrained network serves as a feature extractor for generic image features, while the two final layers are fully-connected layers for classification. This structure is known as a single transfer learning network. It is shown in Fig. 11.

Fig. 11. SINGLE TRANSFER LEARNING NETWORK

Following pretraining, we create a 2048-dimensional feature vector.

Lastly, the feature vector is feeded into two fully-connected layers for classification. We adjust the classification architecture by adding a output layer. This modification improves our network's learning capabilities and helps us to adopt the generic features extracted by the pretrained CNN to the image data.

The output layer has 9 neurons to represent one neuron for each class. To summarize, we propose a transfer learning network structure based on feature extraction and design a two layer fully-connected structure for generic feature adoption to tomato plant leaf image data. The maximum

number of epochs has been selected as 50 in all experiments. The learning rate has been selected as 0.01. Fig. 12 shows the entire architecture of the proposed network.

Fig. 12. ARCHITECTURE OF PROPOSED NETWORK

V. EXPERIMENT AND RESULTS

In this research, to get the most accurate result, we trained and tested our data set with 4 different CNN architectures namely LeNet, AlexNet, VGG16 and ResNet152.

- **LeNet**- LeCun et al. first proposed the LeNet architecture in their paper Gradient-Based Learning Applied to Document Recognition, published in 1998. LeNet CNN architecture consists of 7 layers. The layer composition is made up of 3 convolutional layers, 2 subsampling layers and 2 fully connected layers.
- **AlexNet**- AlexNet architecture is made up of 5 convolutional layers, 3 max-pooling layers, 2 normalization layers, 2 fully connected layers, and 1 softmax layer.
- **VGG16**- VGG16 architecture was used to win ILSVR(ImageNet) competition in 2014. It has 16 layers that have weights. VGG16 focused on having convolution layers of 3x3 filter with a stride 1 and always used same padding and maxpool layer of 2x2 filter of stride 2. It follows this arrangement of convolution and max pool layers consistently throughout the whole architecture. In the end it has 2 fully connected layers followed by a softmax function for output.
- **ResNet152**- ResNet, also known as Residual Neural Network, is a concept that combines residual learning with the traditional convolutional neural network to solve the problem of vanishing gradient and accuracy degradation (training set) in deep networks, allowing both accuracy and speed to be controlled as the network gets deeper and deeper.

Table 1 shows the results for different CNN architecture used.

TABLE 1
EXPERIMENT AND RESULTS

Architecture	Training Accuracy	Testing Accuracy
LeNet	95.87%	77.24%
AlexNet	97.59%	89.54%
VGG16	97.59%	93.49%
ResNet	98.33%	94.01%

VI. CONCLUSION

In this paper, we have proposed a plant leaf disease detection technique using ResNet152 CNN architecture. We also compared our proposed system with several traditional classification methods. The proposed method achieves better accuracy of classification (94.01%) as compared to the best competitive method. Since transfer learning is used, the proposed approach produces good classification results without the need to train deep neural networks from the ground up.
